Abstract

In this study, conducted at the Ser.T of Portomaggiore (Ferrara) between 1998 and 2001, the results of a series of tests were compared. The tests had been carried out during two phases, at the distance of one year, on heroin abusers who had been drug-free for at least two months at the time of the test. The tests include: WAIS, The Rorschach Test, BDHI, SCL-90, TCI and SCID-II (DSM-III-R). The aim of this research was to evaluate which changes can be noted in the files of the subjects, one year after the first administration and after the drug addiction has been abandoned.
